

Computed stability labels differ in how well they support nanobody melting-temperature (T_m) prediction

1. MD data sets (frozen-encoder comparison)

2. Computed property (frozen and fine-tuned encoders)

	frozen encoder	fine-tuned encoder
--	----------------	--------------------

free energy (FEP)	-0.22 CI below 0	-0.15 CI includes 0
-------------------	---------------------	------------------------

native-contact Q (MD)	-0.20 CI below 0	+0.03 CI includes 0
-----------------------	---------------------	------------------------

FEP had the lowest MAE in both settings. Only the frozen-encoder FEP and MD intervals were below zero.
